Meet. Match. Move.

Problem

Running is often seen as a solo activity, but for many, running can feel isolating and unsafe - especially in unfamiliar environments or at odd hours. While social fitness apps exist, they rarely offer personalized matching.

As a result, runners often struggle to find compatible running buddies in their local communities. This lack of connection can hinder motivation, consistency, and the overall enjoyment of running.

Target User Group

Our target users are runners who want to find compatible partners or groups to run with for social connection, motivation, training support, or safety.

They often struggle to find others who match their pace, schedule, and running style. Many feel unsafe running alone, especially at night, and lack structured tools to connect with others nearby.

Users can customize their profile so that they match with users of similar priorities.

Run Tracking

Find Runners

Invite Friends

(From left to right) The app keeps track of your scheduled and past runs. You can use the “Find Runners” tab to match with other runners that may be compatible with your profile. Under the “Create Run” tab, you can schedule a run with all your friends that you have made along the way within the app.

Design Evolution

Whiteboard/Paper Sketch:

Our first sketch was solely centered around “pairing” and having filters for running criteria, similar to an online dating app design. Runners could view potential running partners through a scrollable feed, and also see their schedules, pace, and other compatibility measures for runners.

Figma Mockup:

Our Figma mockup included how users would develop their profile and how users might see potential matches. We also added another way for users to interact with their matches by adding the Party Run feature.

After heuristic feedback, we also decided to add a navigation bar and other labels to make our app more intuitive and less vague.

Our original paper storyboard which guides through matching one user with another compatible user.

Various workflows were prototyped in Figma to determine how users develop their profiles, how users matched and viewed other profiles, and create party runs by interacting with a users' existing matches.

The various core functionalities that our final app - from keeping track of your running activity to matching with other compatible runners - these are some more screenshots of our prototype in use.

Final Prototype

Our final prototype implements the core flows of RunLink: creating and customizing profiles, matching with compatible runners based on pace and availability, and scheduling runs with friends. We built the frontend using React, focusing on mobile usability and intuitive navigation. While some features (like real-time run tracking) are not fully functional, the prototype simulates the complete user journey and demonstrates how users can connect, chat, and plan runs all in one place.
